### **Abstract**

Existing methods of partitioning the market index into bull and bear regimes do not identify market corrections or bear market rallies. In contrast, our probabilistic model of the return distribution allows for rich and heterogeneous intraregime dynamics. We focus on the characteristics and dynamics of bear market rallies and bull market corrections, including, for example, the probability of transition from a bear market rally into a bull market versus back to the primary bear state. A Bayesian estimation approach accounts for parameter and regime uncertainty and provides probability statements regarding future regimes and returns. We show how to compute the predictive density of long-horizon returns and discuss the improvements our model provides over benchmarks. This article has online supplementary materials.

Long-horizon returns

Markov switching

Predictive density

#### **ACKNOWLEDGMENTS**

The authors are grateful for comments from the editor, associate editor, and two anonymous referees, Christos Ntantamis, Richard Paap, Hao Zhou, and participants at the Bayesian Econometrics in Macroeconomics and Finance conference at Erasmus University, the Bayesian Econometrics workshop at Rimini Centre for Economic Analysis (RCEA), the Canadian Econometrics Study Group, the Third Risk Management Conference, Mont Tremblant, and seminar participants from the University of Colorado, Brock University, and McMaster University. We thank the Social Sciences and Humanities Research Council of Canada for financial support.
