### Abstract

We hypothesize and find that (1) earnings conservatism, the tendency of firms to recognize bad news in earnings on a more timely basis than good news, is substantially greater in portfolios of firms with lower price-to-book ratios than in portfolios of firms with higher price-to-book ratios; and (2) the negative association between earnings conservatism and the price-to-book ratio stems primarily from the accrual component of earnings, not the operating cash flow component of earnings. Our results suggest that studies using earnings-returns associations to investigate cross-sectional or time-series differences in earnings conservatism risk drawing erroneous inferences unless the research designs control for cross-sectional or time-series variation in price-to-book ratios.
