Abstract

Purpose

This paper aims to estimate the impact of job search on the internet on the probability of re-employment and the duration of unemployment spells.

Design/methodology/approach

The study uses national panel datasets from Germany (SOEP 2003-2007) and South Korea (KLIPS 1996-2006) to estimate probit and Hausman-Taylor IV models of the impact of job search on the internet on the probability of re-employment. The study also explores duration analysis with the aim of estimating the impact of internet job search on the duration of unemployment.

Findings

In Germany and South Korea job seekers who used the internet had a 7.1 and 12.7 percentage point higher probability, respectively, of being re-employed in the next 12 months. Furthermore, job seekers who used the internet had a shorter duration of unemployment in both Germany and South Korea.

Practical implications

Over the past decade, internet penetration rates and use of the internet in job search have risen sharply across the world. The internet has significantly changed the job application process and improved the channels of communication between employers and job seekers. The findings of the research indicate that the internet is beneficial and should be a part of job search efforts.

robust to unobserved heterogeneity problems. The study also addresses the issue of endogeneity of job search on the internet by using the Hausman-Taylor IV model.
