ABSTRACT

The Variance Inflation Factor and the Condition Number are measures traditionally applied to detect the presence of collinearity in a multiple linear model. This paper presents the relation and the difference between both measures from theoretical and empirical perspectives by using Monte Carlo simulations and taking special interest in the computational techniques.

Notes

1 Note that the constant term disappears after the standardization of the data.

2 Note that, when data are standardized, the VIF and CN coincide with the result obtained from typified data.

3 Note that these examples are not regression models since $n=p$.

4 Denoting $X_1=1$, the auxiliary regression to calculate the VIF is expressed as $X_2=\gamma_1+w$, where it is verified that $\hat{\gamma}=X^{-2}$ and, consequently, $SSR=\sum_{i=1}^n(X_{2i}-X^{-2})^2=SST$. In this case, it is always verified that $R_{aux}^2=1$. The version of the previous regression with unit length data is given by $X_{2,lu}=\gamma_{1lu}+w$ where $X_{2,lu}=X/a$ with $a=\sum_{i=1}^n X_{2i}^2$ and $1_{lu}=1/n$. In this case, $\hat{\gamma}=n/a \cdot X^{-2}$ and, then, $SSR=(1/a)\sum_{i=1}^n(X_{2i}-n \cdot X^{-2} \cdot 1/n)^2=SST$. Thus, this situation will be similar to the initial one.
