Abstract

Repressors have shown short-term tolerance of acute pain but long-term sensitivity to chronic pain. To reconcile this discrepancy, we hypothesised that repressors routinely suppress pain-related thoughts during acute pain, and thus paradoxically incur rebound effects (increased accessibility of the to-be-suppressed material) afterwards. Healthy individuals ($n=222$) were assigned to suppress or not suppress pain-related thoughts during a cold pressor. Recovery and exposure to a massage device followed. Repressors revealed evidence of habitual suppression: nonsuppression/repressors showed a pattern of slow recovery from the cold pressor and unfavourable responses to the massage device similar to that exhibited by suppression/high anxious participants; suppression/repressors showed the slowest recovery and found the massage more unpleasant than any group. Repressors may suffer long-term sensitivity to pain through

rebound and contamination effects following attempts to suppress pain-related thoughts.
