Abstract

A Hodgson's hawk-eagle (*Spizaetus nipalensis*) reared by a falconer showed severe weakness with multiple fractures of bone. It had a history of being fed an all-meat diet. Serological examination revealed a hypocalcaemia (72.0 µg/ml), and hypophosphataemia (29.0 µg/ml). Gross and microscopic examinations demonstrated severe osteodystrophia fibrosa (fibrous osteodystrophy) characterized by osteoclastic bone resorption.

and calcium compound by oral administration. Biochemical examination eight days later revealed lower serum calcium (72.0 µg/ml) and phosphorus (29.0 µg/ml) and higher alkaline phosphatase (ALP) (3100 IU/l) than normal. Normal ranges of these inorganic substances or enzyme in raptors are 89.3–101.9 µg/ml (calcium), 30.3–43.4 µg/ml (phosphorus) and 31–257 IU/l (ALP), respectively (Samour, [2000](#)). The bird died ten days after the initial examination.

Gross examination confirmed that bone was very fragile with multiple complete and/or incomplete fractures. The parathyroid glands were bilaterally enlarged, up to 6 mm in diameter, and they were even larger than thyroid glands.

Histological changes of the affected bone mainly consisted of osteomalacic lesions and fractures. The former was characterized by a significant decrease in the amounts of mineralized trabecular bone associated with an increase in the width of unmineralized osteoid ([Fig. 1](#)). The osteoid borders were occasionally lined by osteoblasts and distinct osteoid seams were recognized. These changes occurred in the cortical and cancellous bone of the sternum, femur and tibiotarsus. The cortical bones of the diaphyses were also markedly thinned with dilation of the Haversian canals. The femur and tibiotarsus partly showed subperiosteal proliferation of trabeculae and loose fibrous tissue ([Fig. 2](#)). In addition, numerous osteoclasts were frequently observed on the surface of the trabeculae, Haversian canals and endosteum and fibrous tissue proliferated between these trabeculae ([Fig. 3](#)), suggesting a progression to osteodystrophia fibrosa. Although there were endochondral and membranous ossifications in and around the necrotic bone of each fracture, mineralization was incomplete in these foci. Enlarged parathyroid glands consisted of proliferation of hypertrophic chief cells, which had lightly eosinophilic and vacuolated cytoplasm ([Fig. 4](#)). Follicles of thyroid glands were atrophic and were lined by cuboidal epithelium.

Fig. 1 Decalcified section of the sternum. Thickened borders of thick unmineralized osteoid (arrow) and thin trabeculae (arrowhead). Haematoxylin and eosin, 100×.

Osteodystrophia fibrosa is the result of continuous and excessive secretion of PTH and is characterized by marked osteoclastic resorption and fibrous replacement (Palmer, [1991](#)). Locomotory disorders with fractures in birds of prey including those for falconry, have been reported as "cramps" or "fits"; protracted dietary deficiency of calcium or imbalance of calcium/phosphorus ratio has been considered important causative factors (Wallach & Flieg, [1970](#); Cooper, [1975](#)). However, pathological descriptions of osteodystrophia fibrosa due to nutritional secondary hyperparathyroidism have rarely been reported in avian species (Long et al., [1983](#)).

The present case was considered nutritional secondary hyperparathyroidism that resulted in severe osteodystrophia fibrosa. The active osteoclastic bone resorption and fibrous tissue proliferation between trabeculae in the examined bones are characteristic findings of osteodystrophia fibrosa. On the other hand, accumulation of osteoid and formation of osteoid seams in the medullary cavity are specific features of osteomalacia, which frequently progresses to osteodystrophia fibrosa when severe hyperparathyroidism develops in the course of the disease (Woodard, [1997](#)). Compensating subperiosteal bone proliferation occurs in some cases of osteopenia (Riddell, [1996](#)). However, subperiosteal proliferation of osteoid and fibrous tissues in the present case was considered as unmineralized reactive callus resulting from microscopic fractures, because it was observed only in part of the femur and tibiotarsus.

The calcium: phosphorus ratio (Ca: P) of meat and fish commonly fed to birds of prey range from 1: 17 to 1: 44 whereas the correct Ca: P ratio for avian diets is listed as 1.5: 1 (Wallach & Flieg, [1970](#)). As exceptionally high dietary levels of phosphorus in these diets maybe from insoluble salts with calcium and prevent their absorption in addition to an absolute calcium deficiency, these diets result in an increased activity of the parathyroid gland for a long term.

Hyperparathyroidism is a disease of the endocrine system. It is characterized by excessive secretion of parathyroid hormone (PTH) from the parathyroid glands. Although it is most commonly seen in domestic animals, it has also been reported in various species of birds, including raptors. The type of hyperparathyroidism seen in birds is usually nutritional secondary hyperparathyroidism, which is caused by an imbalance of calcium and phosphorus in the diet. This condition is characterized by bone resorption and fibrous replacement of bone tissue, leading to osteodystrophia fibrosa. The clinical signs of this disease include weakness, lameness, and fractures. The diagnosis is usually based on clinical signs, radiographic findings, and blood chemistry. The treatment involves correcting the dietary imbalance and, in some cases, surgical removal of the parathyroid glands. It is important for the

For a long time, falconry has been maintained throughout the world as a traditional form of hunting and the avian species used include hawks, eagles, buzzards and peregrines. Dietary requirements of raptors have not been sufficiently studied, but artificial diets such as muscle meat and eviscerated prey are known to lack vitamins, calcium and phosphorus and may cause various metabolic bone diseases in raptors (Keymer, [1972](#); De Water, [1996](#)). Investigation of the dietary requirements of raptors is essential to preserve these rare birds.

Acknowledgments

The authors would like to thank Dr C. Itakura of the Institute of Physical and Chemical Research, Wako, Japan, for his suggestions.
