Abstract

We provide a self-contained analysis of a class of continuous-time stochastic mortality models that have gained popularity in the last few years. We describe some of their

We Care About Your Privacy

We and our 848 partners store and/or access information on a device, such as unique IDs in cookies to process personal data. The financial support of the Belgian Government under the contract 'Projet d'Actions de Recherche Concertées' ARC 04/09-320 is gratefully acknowledged by Michel Denuit and Pierre Devolder. This work was partly done when Enrico Biffis visited the Institute of Actuarial Science at the University of Louvain, supported by ARC 04/09-320. Michel Denuit also thanks the Banque Nationale de Belgique for financial support.

Notes

1. This may be the case even with deterministic death rates: large portfolios may reduce to classes of very few policies once contracts are disaggregated by relevant risk characteristics; in secondary markets, portfolios that are very large in value may contain very few homogeneous contracts (e.g. Life Settlements portfolios).
2. All filtrations are assumed to satisfy the usual conditions, i.e. right-continuity and completeness.
3. In the following, we use the notation \mathcal{F}_t for \mathcal{F}_t .
4. That is, for all t . We use the notation $t \wedge s := \min(t, s)$ throughout the paper.
5. We consider its right-continuous-with-left-limits modification.
6. We use the convention that \int_0^t stands for integration over $(0, t]$.
7. With regard to (A1), we mean that μ may not be continuous.
8. A situation of deterministic intensity μ is deterministic.
9. See [Biffis et al. \(2010\)](#).
