Abstract

We consider the problem of evaluating variable annuities with a guaranteed minimum withdrawal benefit under a regime-switching model. We propose a trinomial lattice model to approximate the evolution of the investment fund value and the policy value at inception is computed through a backward induction scheme. Finally, the insurance fee is computed as the solution of the equation that makes the contract actuarially fair. Numerical results are reported to illustrate the consistency of the proposed model.

Keywords:

minimum guaranteed withdrawal benefit

variable annuities

regime-switching models

Notes

No potential conflict of interest was reported by the author.

- 1 In the case of $\beta < 1$, we set $\beta = 1$, hence $\beta = 1$. In other words, once the reference fund reaches zero it stays trapped there until maturity.
- 2 The existence of the solution is shown in the Appendix [4](#).
