Abstract

Diminishing marginal returns (DMR) to school inputs could explain a wide variety of findings in the research literature. One important example is the influential finding by Heyneman and Loxley that school inputs are the 'predominant influence' on achievement in developing nations, where input levels are low, even though the same

school inputs are high in developed nations. This paper tests for the presence of DMR in a sample of 32 developing nations. The results show that DMR is present in 27 of the 32 nations. The magnitude of the DMR is related to the level of school inputs. The results suggest that DMR is a common phenomenon in developing nations. The results also suggest that DMR is related to the level of school inputs. The results suggest that DMR is a common phenomenon in developing nations. The results also suggest that DMR is related to the level of school inputs.

Acknowledgements

The author wishes to thank Martin Carnoy, Cassandra Guarino, Stephen Heyneman, Patrice Iatorola, David Plank, Tim Sass, and participants in sessions at Florida State University, the American Education Finance Association, and Association for Public Policy and Management for valuable advice. Two anonymous referees also provided valuable feedback. The author is responsible for all remaining errors.

Notes

1. The average country in Europe spends approximately 3.6% of the Gross Domestic Product on primary and secondary education (Organization for Economic Cooperation and Development, [2003](#)). The value is 4% for a sample of 10 developing nations.
2. For example, Murnane et al. ([1995](#)), Currie and Thomas ([1999](#)), and Neal and Johnson ([1996](#)) find a positive link between academic test scores and the wages of individual workers in the United States. Psacharopoulos ([1985](#)) finds a positive relationship between years of education and income in developing countries in an extensive review of research. Hanushek and Kimko ([2000](#)) find evidence that countries with higher academic achievement also have higher economic growth rates.
3. A related influential result is that there are diminishing economic returns to years of education, holding school inputs constant (Psacharopolous, [1985](#)). This should not be confused with the result that higher academic achievement leads to higher economic growth, which is true for developing nations (see [Psacharopoulos and Hoxby, 2004](#)).
4. Some studies, such as those by Dewa and Hoxby (2004) and Hoxby (2000), find that the effect of class size on test scores is small. For example, Dewa and Hoxby (2004) find that a one standard deviation increase in class size has a meta-analysis estimate of the average effect of reducing class size by one student for one
5. Harris and Kolesky (2004) find that a one standard deviation increase in class size has a meta-analysis estimate of the average effect of reducing class size by one student for one

grade is 0.0008–0.0020 test score standard deviations. The same study compares these results with a sample of non-experimental estimates: Akerhielm ([1995](#)), Dolan and Schmidt ([1987](#)), Eide and Showalter ([1998](#)), Ehrenberg and Brewer ([1994](#)), Ferguson ([1991](#)), Goldhaber and Brewer ([1997](#)), and Hanushek et al. ([1996](#)). Harris finds that very few of these non-experimental estimates of the class size effect are within the range identified from the experimental literature; and nearly all are below it.

6. The results in the Tennessee STAR experiment are not available by race.

7. Hanushek and Luque write that ‘it has been conventionally held, particularly following Heyneman and Loxley ([1983](#)), that schools and school resources are more important than families in developing countries’ (2003, p. 498).

8. An alternative possibility, not tested by Heyneman and Loxley, is that there may be weaker correlations between measures of socioeconomic status and actual home environment in poor countries. Heyneman and Loxley seem to highlight this possibility when they write that ‘the pressure on students to do well on examinations does not appear to vary as markedly on the basis of parental socioeconomic status’ ([1983](#), p. 1183). They provide no statistical tests of this, however.

9. One argument for testing input effects by national income level is that the latter may be a proxy for school input levels. Yet, if one is interested in DMR in school inputs, then it would seem better to interact school inputs with themselves directly, as in the analysis that follows. Income might also be seen as a measure of non-school inputs (socioeconomic status), but in this case it would seem preferable to use measures at the individual level, rather than national income, as in Baker et al. and Hanushek and Luque. For Baker et al., this is apparently a test of the ‘social reproductive process,’ referring to the tendency of societies to give greater educational opportunities to those children who already have the greatest advantage, but it is still unclear how their

scores across students (or across time within students) actually mean (McCaffrey et al., 2003). The author wishes to thank an anonymous referee for raising this point.

11. Figlio's plots the marginal effects of class size and teacher salaries as various input levels, and finds, for instance, that the class size effect is relatively unaffected by most input levels, except school size (number of students in the school). DMR does appear to be present in teacher salaries with respect to parent income levels and perhaps instructional hours. Figlio does find that the class size effect becomes larger in schools that have more students.

12. The standard errors for y_1 , y_2 , and y_3 were estimated using the 'stdp' command in Stata. Note that the subscript on the sample size becomes irrelevant because the sample size is the same for each prediction within each country.

13. To see why this is the case, note that as a matter of notation. Also, is true by assumption and is true because of the constant returns assumption. Thus, and, by substitution, it is therefore true that is exactly equal to $\Delta y_H^{CMR} - \Delta y_H^{DMR}$.

14. Hanushek et al. (1996) show that the studies finding the largest effects of school resources are based on data aggregated to the state level and, to a lesser extent, the district level. Such high levels of aggregation had been defended on the grounds that they reduce measurement error. They show both empirically and theoretically, however, that lower levels of aggregation reduce the effects of omitted variables; and the higher measurement error is likely to be inconsequential. Their empirical analysis therefore starts with a model of student-level test scores, explained by various student-level characteristics and school-level characteristics. This is the approach implied in the equations above and used throughout the present analysis. Hanushek and Luque (2003), in contrast, estimate a single equation in which student-level variables are aggregated upwards to the classroom level. No justification is given for this choice.

17. The input indices were created by placing each of the input variables on a 0-1 scale, summing and dividing by the number of variables (for school and non-school categories, respectively). The national income data are taken from World Bank ([1996](#)).
