Abstract

This article contributes to public and policy debates on the value of social media disruption activity with respect to terrorist material. In particular, it explores aggressive account and content takedown, with the aim of accurately measuring this activity and its impacts. The major emphasis of the analysis is the so-called Islamic State (IS) and disruption of their online activity, but a catchall "Other Jihadi" category is also utilized for comparison purposes. Our findings challenge the notion that Twitter remains a conducive space for pro-IS accounts and communities to flourish. However, not all jihadists on Twitter are subject to the same high levels of disruption as IS, and we show that there is differential disruption taking place. IS's and other jihadists' online activity was never solely restricted to Twitter; it is just one node in a wider jihadist social media ecology. This is described and some preliminary analysis of disruption trends in this area supplied too.

Internet companies have responded both individually and collectively. On 26 June 2017, Facebook, Microsoft, Twitter, and YouTube jointly announced, via an agreed text posted on each of their company's official blogs, the establishment of the Global Internet Forum to Counter Terrorism (GIFCT).[4] They described the purpose of the GIFCT as "help[ing] us continue to make our hosted consumer services hostile to terrorists and violent extremists" and went on to state: "We believe that by working together, sharing the best technological and operational elements of our individual efforts, we can have a greater impact on the threat of terrorist content online."[5] In terms of individual companies' responses, in November 2017 Facebook published a blog post in their "Hard Questions" series addressing the question "Are We Winning the War on Terrorism Online?" Facebook announced in the post that it is able to remove 99 percent of IS and Al Qaeda material prior to it being flagged by users "primarily" due to advances in artificial intelligence techniques. Once Facebook becomes aware of a piece of terrorist material, it removes 83 percent of "subsequently uploaded copies" within an hour of their being uploaded, the company said.[6] Missing from the update however were figures on how much terrorist content (e.g., posts, images, videos) is removed from Facebook on a daily, weekly, or monthly basis. Twitter is much less reticent on this point.

According to the section "Combating Violent Extremism" in Twitter's twelfth Transparency Report, published in September 2017, in the period 1 January to 30 June 2017:

> ... a total of 299,649 accounts were suspended for violations related to promotion of terrorism, which is down 20% from the volume shared in the previous reporting period. Of those suspensions, 95% consisted of accounts flagged by internal, proprietary spam-fighting tools, while 75% of those accounts were suspended before their first tweet.[7]

All told, Twitter claim to have suspended a total of 1,210,357 accounts for "violations related to the promotion of terrorism" in the period from 1 August 2015 to 31 December 2017.[8]

A disparity therefore exists between the assertions of policymakers, on the one hand, and major social media companies, on the other, as regards the levels and significance of their disruption activity. Although Twitter claims severe disruption of IS is occurring on their platform, detailed description and analysis of the precise nature of this disruption activity and, importantly, its effects are sparse,[9] particularly within the academic literature. This article aims to contribute to public and policy debates on the value of disruption activity, particularly aggressive account and content takedown, by seeking to accurately measure this activity and its impacts. The research findings challenge the notion that Twitter remains a conducive space for IS accounts and communities to flourish, although IS continue, to some lesser extent, to distribute propaganda through the channel. Not all jihadists on Twitter are subject to the same high levels of disruption as IS; however, this research demonstrates that a level of differential disruption is taking place. Additionally, and critically, the online presence of IS and other jihadists is not restricted to Twitter. The platform is merely one node in a wider jihadist online ecology. The article describes and discusses this, and supplies some prelimin...

If a tweet matched these search criteria, it was automatically analyzed to determine if it was relevant, using a machine-learning classifier trained to mimic the classification decisions of a human analyst.[11] A key task of the relevancy classifier was to separate target Twitter accounts from other Twitter accounts using similar language, such as those held by journalists or researchers, for example. If the tweet was deemed as relevant, further historic tweets were automatically extracted for the candidate account and assessed for relevancy (see step (ii) in Figure 1), providing the system with an aggregate view of the tweet history of the account. This overview of the tweet history was combined with other account metadata that could be extracted. These pieces of information were scored automatically and candidate Twitter accounts that exceeded the set thresholds were presented to a human analyst for decision (see step (iii) in Figure 1). As portrayed in step (iv) in Figure 1, if one of the research analysts on the project confirmed that the account was pro-jihadist, then the out-links contained in all of the account's tweets were automatically analyzed, and details of the account, its tweets, and its links were stored in the database (see step (v) in Figure 1).

Information from new confirmed accounts was used by the system in a feedback loop to continually improve its efficiency, thereby identifying new seed search terms (see step (vi) in Figure 1) and providing additional seed accounts (see step (ii) in Figure 1).

Caveats

There were, however, a number of caveats attached to the data-collection that deserve mention. First, the bulk of the data was gathered over two months in early 2017 (February to April). The system to implement the semi-automated methodology was created, tested, and evolved throughout this period. The online accounts returned by the system were integrated with those found via traditional, manual search for accounts of interest. The overall approach was, therefore, a combination of automated and manual, and snowball and purposive sampling methods.

Data

The research dataset comprised 722 pro-IS accounts (labeled Pro-IS hereafter) and 451 other jihadist accounts (labeled "Other Jihadist" hereafter), with at least one follower[14] active on Twitter at any point between 1 February and 7 April 2017 (see Table 1). Accounts were determined to be Pro-IS if their avatar or carousel images contained explicitly pro-IS imagery and/or text, and/or at least one recent tweet by the user (i.e., not a retweet) contained explicitly pro-IS images and/or text, such as referring to IS as "Dawlah" or their fighters as "lions." Accounts maintained by journalists, academics, researchers, and others who tweeted, for example, Amaq News Agency content for informational purposes, were manually excluded. The Other Jihadist category included, among others, those supportive of Hay'at Tahrir al-Sham (HTS), Ahrar al-Sham, the Taliban, and al-Shabaab. Similar parameters were employed to categorize these accounts.

Table 1. Description of final dataset.

Download CSV   Display Table

Accounts in the research database were located and identified in three different ways (see Table 2). The first set of accounts was manually identified by the research team, principally by examining known jihadi accounts (or those known to be of interest to jihadi supporters) and inspecting accounts within their networks (i.e., those following or being followed by them). A second group of accounts was identified "semi-automatically"—that is, automatically by the above-described social media monitoring system and then manually inspected by a human analyst who confirmed: (a) whether or not they were jihadist accounts; and (b), if they were, of what type. Several approaches were used to identify or generate seed accounts. This included analyzing vocabulary used in known jihadi accounts that were active during the time period studied or had recently been active. This enabled the team to determine which terms were being used much more often than would be expected statistically, and searching for tweets that contained these terms. These candidates were then winnowed based on the relevancy of their tweets in general (see above) and other metadata. Finally, a third set of accounts was identified automatically by the social media monitoring system, based on the presence of known IS propaganda links (i.e., Uniform Resource Locators [URLs] linking to official IS content hosted on some other platform or in some database on the Internet). These links were first identified through other tracking procedures, including (but not limited to) being spotted in confirmed IS tweets.

Twitter w... ...blishment of their so-called ...IS Twitter accounts active in... ...ion by Twitter from

throughout 2015 and 2016. From mid-2015 through January 2016, for example, Twitter claimed to have suspended in the region of 15,000 to 18,000 IS-supportive accounts per month. From mid-February to mid-July 2016, this increased to an average of 40,000 IS-related account suspensions per month,[17] according to the company.[18] Despite the growing costs attached to remaining on Twitter (such as greater effort to maintain a public presence while relaying diffused messages and deflated morale), during this period IS supporters routinely penned online missives exhorting "Come Back to Twitter."[19] The question raised here is whether, in 2017, it was any longer worthwhile for pro-IS users to continue to seek to retain a presence on the platform?

Until now, the small amount of publicly available research on the online disruption of IS has focused on the impact of Twitter's suspension activities on follower numbers for reestablished accounts.[20] As well as updating these data, this research also examined the longevity or survival time of accounts, and compared Pro-IS to Other Jihadist accounts on both measures (i.e., follower numbers and longevity). The overall finding was that IS-supportive accounts were being significantly disrupted, which in turn has effectively eliminated IS's once vibrant Twitter community. Differential disruption is taking place, however, meaning Other Jihadist accounts were subject to much less pressure.

Account Longevity

This section addresses the survival time of accounts in the research database. All were active at the point they were identified and classified as Pro-IS or Other Jihadist. Once an account was added to the database, its status was monitored and the system recorded when it was suspended, if this subsequently occurred. This enabled the research team to measure the age of each account (i.e., the time elapsed since the account's creation) at the date of suspension. Worth underlining here is that the below-described survival rates of Pro-IS accounts would likely have been considerably shorter if the analysis included those accounts suspended—often within minutes of creation—before they could be captured by the research team for inclusion in the dataset.

Figure 2 depicts the estimated cumulative suspension rate for all Twitter accounts in the dataset, outlining the probability of an account being suspended against its age (represented in days) for the 722 Pro-IS accounts and 451 Other Jihadist accounts. The majority—around 65 percent—of Pro-IS accounts were suspended before they reached 70 days since inception. At the same time point, less than 20 percent of Other Jihadist accounts had been suspended. In fact, in terms of differential disruption, more than 25 percent of Pro-IS accounts were suspended within five days of inception; a negligible number (less than 1 percent) of Other Jihadist accounts were subject to the same swift response.

Figure 2. Cumulative suspension rate for all accounts in database.

Display fu...

The cate...ible that others may

eventually suspended: 455 Pro-IS accounts and 163 Other Jihadist accounts. The rationale is that these accounts were independently judged to have breached Twitter's terms of service. Again, regarding differential disruption, the data illustrates that 85 percent of Pro-IS accounts were suspended within the first 60 days of their life, compared to 40 percent of accounts falling into the Other Jihadist category. Further, more than 30 percent of Pro-IS accounts were suspended within two days of their creation; less than 1 percent of Other Jihadist accounts met the same fate.

Figure 3. Cumulative suspension rate for accounts eventually suspended.

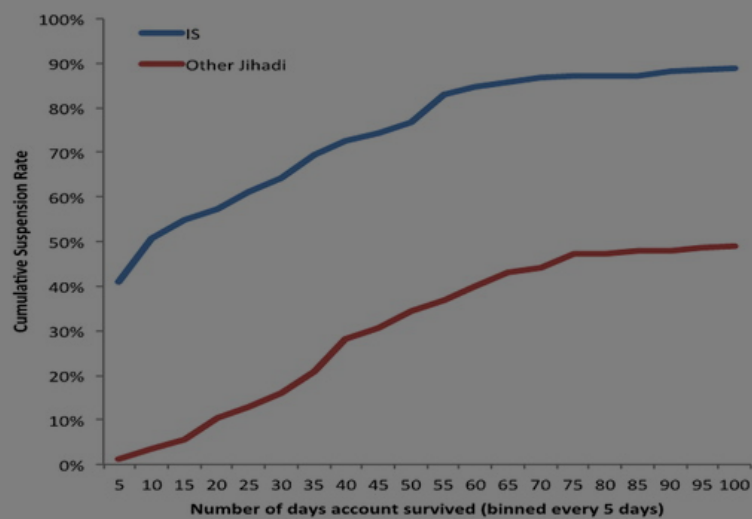

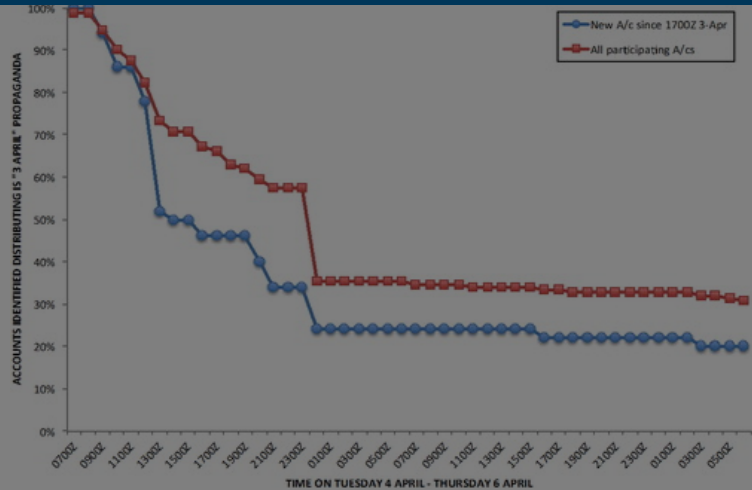

Display full size

Further analysis of suspended accounts revealed that the three subsets of Pro-IS accounts (i.e., those identified manually, semi-automatically based on general tweet content, and advanced semi-automatically as a result of linking to official IS propaganda) also displayed different survival and activity patterns. From the 722 Pro-IS accounts in the dataset, the manually identified accounts (27 percent) survived disruption for longer periods and were primarily tweeting about general IS and non-IS related news. The accounts identified through semi-automated means (30 percent) had a somewhat shorter lifespan and were tweeting content generically related to IS involvement in the Syria conflict, including daily battle updates from several of what were then IS frontlines, such as Mosul, Al-Bab, Deir Ez-Zor, and eastern Aleppo. Accounts located via advanced semi-automated means (43 percent) experienced the shortest lifespans. They were initially identified as a result of sending at least one tweet specifically disseminating "official" IS propaganda (e.g., from the Amaq News Agency). Many were thus found to be exclusively tweeting links to official IS propaganda.

Mini-Case Study: Intervention Effectiveness

Figure 4.

Display full size

On Monday, 3 April 2017, IS uploaded its daily propaganda content to a variety of social media and online content-hosting platforms. This content generally included videos (in daily news format and other propaganda videos), "picture stories" (a photo montage that tells a story), brief pronouncements similar to short press releases, radio podcasts, and other documents (e.g., magazines). Over the course of Monday afternoon and evening, 153 unique Twitter accounts were identified that sent a total of 842 tweets with links to external (non-Twitter) Web pages, each loaded with an item or items of IS propaganda. It was found that only 10 of those Twitter accounts (7 percent) were independent, third-party "mainstream" accounts. The balance of accounts was identified as pro-IS. Fifty of these appeared to be throwaway accounts (i.e., accounts with no followers set up solely to distribute propaganda and sending only IS propaganda tweets until suspended) created on Monday evening.

Method 52 was used to track all accounts disseminating this propaganda—those sending one or more tweets with a 3 April propaganda link at some point prior to 06.00 GMT on the morning of Tuesday, 4 April 2017. Figure 4 shows the survival curves for all 153 Twitter accounts tweeting IS propaganda from Monday, 3 April and for the subset of 50 throwaway accounts specifically created on the Monday evening. The data shows that at 07.00 GMT on Tuesday, 4 April 2017, 100 percent of these accounts were active. However, by 13.00 GMT, this figure had reduced to just 73 percent, falling to 58 percent by 23.00 GMT. This then dropped sharply to 35 percent surviving un-suspended by midnight on Tuesday. Very few of these surviving accounts were suspended over the subsequent 48 hours tracked. The fifty throwaway accounts created on Monday evening specifically to disseminate propaganda were suspended or deleted even faster: by 13.00 GMT only 52 percent were still active, falling to 34 percent by 23.00 GMT and 24 percent by midnight on Tuesday.

This demonstrates that the response to official IS propaganda being distributed via Twitter was reasonably effective in terms of identifying and taking down disseminator accounts in the first 24 hours after they linked to official IS content. Pro-IS ac   red to those Pro-IS accounts   operating on a 24-hour "ne   da. As these accounts   eated and used to distribut   ve permanent traces o   broadcast links to its d

Commu

What are   rates for Pro-IS accounts   punts in the dataset and com   tive, this means

To demonstrate this, Table 3 compares the median number of tweets, followers, and friends[24] of Pro-IS accounts versus those of Other Jihadists. The short lifespan of Pro-IS accounts meant that many had only a small window in which to tweet, gain followers, and follow other accounts. This meant Other Jihadist accounts had the opportunity to: send six times as many tweets; follow or "friend" four times as many accounts; and importantly, gain 13 times as many followers as the Pro-IS accounts. An even more stark comparison is between median figures for Pro-IS accounts in 2017 versus those recorded for similar accounts in 2014. The median number of followers for pro-IS accounts in 2017 was 14 versus 177 in 2014,[25] a decrease of 92 percent. The median number of accounts followed by IS supporters in 2014 was 257, whereas this research found a median of thirty-three "friends" per pro-IS account—a decrease of 87 percent.[26] In an analysis of 20,000 IS supporter accounts in a five-month period between September 2014 and January 2015, Berger and Morgan observed suspension of just 678 accounts,[27] a total loss of 3.4 percent. In the research dataset outlined in this article, the total loss of Pro-IS accounts in just four months (between January and April 2017) was conservatively 63 percent.

Table 3. Median number of tweets, followers, and friends for accounts not yet suspended.

Download CSV   Display Table

Throughout what may be referred to as the IS Twitter "Golden Age" in 2013 and 2014, a variety of official IS "fighter" and an assortment of other IS "fan" accounts were accessible with relative ease. For the uninitiated user, once one IS-related account was located, the automated Twitter recommendations on "who to follow" accurately supplied others.[28] For those "in the know," pro-IS users were easily and quickly identifiable through their choice of carousel and avatar images, along with their user handles and screen names. Thus, if one wished, it was quick and easy to become connected to a large number of like-minded other Twitter users. If sufficient time and effort was invested, it was also relatively straightforward to become a trusted—even prominent—member of the IS "Twittersphere."[29] Not only was there a vibrant overarching pro-IS Twitter community in existence at this time, but also a whole series of strong and supportive language (e.g., Arabic, English, French, Russian, Turkish) and/or ethnicity-based (e.g., Chechens or "al-Shishanis") and other special interest (e.g., females or "sisters"[30]) pro-IS Twitter sub-communities. Most of these special interest groups were a mix of: a small number of users on the ground in the "caliphate"; a larger number of users wanting to travel to the "caliphate" (or with a stated preference to do so); and an even larger number of "jihobbyists."[31] The latter had no formal affiliation to any jihadist group, but spent their time lauding fighters, celebrating suicide attackers and other "martyrs," and networking around and disseminating IS content.

In 2014, pro-IS accounts were already experiencing some pressure from Twitter; for example, official IS accounts were some of the first to be suspended that summer. Twitter's disruption activity increased significantly over time, forcing pro-IS us_____ces, remain active, and pres_____rticular hashtags, such as _____ed users to the platform_____g these hashtags in their dis_____rters' resolve and they bec_____ng this time, susp_____ve resulted in decr_____nit and unified commu_____upport to do so.[33]

suspension. Even those who persisted were forced to take countermeasures such as locking their accounts so they were no longer publicly accessible, or diluting the content of their tweets so their commitment to IS was no longer so readily apparent. By April 2017, these measures had taken such hold that the vast majority of Pro-IS account avatar images were default "eggs" or other innocuous images, and many of the account user handles and screen names were meaningless combinations of letters and numbers (see Table 4).[35] A conscious, supportive, and influential virtual community is almost impossible to maintain in the face of loss of access to such group or ideological symbols and the resultant breakdown in commitment. As a result, IS supporters have re-located their online community-building activity elsewhere, primarily to Telegram, which is no longer merely a back-up for Twitter.[36]

Table 4. Changes in account name types due to disruption activity.*

Download CSV   Display Table

From a quantitative perspective, the data discussed in this section demonstrate three key findings. First, IS and their supporters were being significantly disrupted by Twitter, where the rate of disruption depended on the content of tweets and out-links. Second, although all accounts experienced some type of suspension over a period of time, Pro-IS accounts experienced this at a much higher rate compared to the Other Jihadist accounts in the dataset. Third, this severely affected IS's ability to develop and maintain robust and influential communities on Twitter. As a result, pro-IS Twitter activity has largely been reduced to tactical use of throwaway accounts for distributing links to pro-IS content on other platforms, rather than as a space for public IS support and influencing activity.

Beyond Twitter: The Wider Jihadi Online Ecology

Research on the intersections of violent extremism and terrorism and the Internet have, for some time, been largely concerned with social media. Studies have often had a singular focus on Twitter due to its particular affordances (e.g., ease of data collection due to its publicness, the nature of its application programming interface), which is problematic.[37] For example, Europol's Internet Referral Unit reported that, as far back as mid-2016, they had identified "70 platforms used by terrorist groups to spread their propaganda materials."[38] This section of the article is therefore concerned with the wider online ecology where IS supporters and other non-IS jihadist users operate, with a particular focus on out-links from Twitter.

Owing partly to its character limit,[39] Twitter can function as a "gateway"[40] platform to other social networking sites and a diversity of other online spaces. In 2014, it was estimated that one in every 2.5 pro-IS tweets contained a Uniform ... e these links, but this was ... out of auto-expandi... he data collected for this rese... cent for Pro-IS and 4,650 on... ntified, one in eight (around ... he 40 percent of tweet... teresting snapshot of th... eriod (see Table 5).

Table

YouTube was the top linked-to platform for both Pro-IS and Other Jihadist accounts, pointing to the overall importance of the site—and of video generally in Web 2.0—in the jihadist online scene. Facebook does not appear in the Top 10 out-links for Pro-IS accounts, albeit a recent report claims that IS content and IS-supportive users are still easily locatable on Facebook.[42] What our findings indicate is that, like Twitter, Facebook is engaged in differential disruption as it is the second most preferred platform for out-linking by Other Jihadists. The somewhat obscure justpaste.it content upload site has been known for some time as a core node in the "jihadisphere,"[43] and its high-ranking status for both Pro-IS and Other Jihadist accounts is thus relatively unsurprising.

Other content upload destinations preferred by Pro-IS users, including Google Drive, Sendvid, Google Photos, and the Web Archive, do not appear in the Other Jihadist Top 10. One particular reason for this is probably the focus of Other Jihadists on linking to traditional proprietary websites, such as the Taliban's suite of sites. It is worth mentioning that, while Telegram slips into the Top 10 for Other Jihadists, only twenty (0.04 percent) of all tweets from Pro-IS accounts contained a telegram.me link. The paucity of such links caused us to explore further; we were surprised to find that just two of 722 Pro-IS users' biographies and two of 451 Other Jihadist users' biographies contained Telegram links. Neither group of accounts were using Twitter to advertise ways into Telegram.

Case Study: Destinations of Official IS Propaganda

As mentioned, during the research period, IS was operating a 24-hour "news cycle," disseminating a daily batch of new official propaganda via social media channels, including Twitter. Links to this propaganda were circulated through tweets and other means. These links pointed to a wide variety of other social media and content hosts that contained newly uploaded propaganda daily. A sample of these propaganda destinations were analyzed at three time points: 4–8 February, 4–8 March (excluding 7 March, see below), and 4–8 April 2017. The research team obtained the full daily roster of IS propaganda and the sites where it appeared for each of these time periods. This allowed the identification of the most frequently linked-to platforms, along with how many pieces of propaganda were posted by host domains, and what proportion of these URLs were subsequently taken down (see Figure 5).

Figure 5. Destinations of official IS propaganda: Number of URLs and URL destinations February to April 2017.
Overall, over these three time periods, Pro-IS users linked to thirty-nine different third-party platforms or sites, as well as IS running its own server[44] to host its propaganda material. It is important to note that the former were exclusively, it is believed, "leaf" destinations. That is, they contained content but no links to other sites, so did not have a networking or community-building aspect. Someone visiting such a page would not be able to discover more about the network of other sites. Important exceptions to this were YouTube and a small number of other sites that algorithmically "recommend" similar content in their inventory, which may have resulted in their pointing to other available IS propaganda.[45] During the period of the research, the average number of URLs populated rose from forty-two per day in February to fifty-two per day in April. This hints at increasing fragmentation and dispersal, possibly in response to takedown activity by a variety of platforms and sites. However, there was a large inter-day variation (twenty to sixty-five) and one outlier day on 7 March was excluded, as it was the publication date of issue 7 of IS's Rumiyah online magazine. On this day, IS pushed 240 separate URLs, a quarter of which contained direct reference to Rumiyah in the link, and many more that probably linked to the new issue of the magazine.[46]

Of the forty domains used (thirty-nine external, one internal server), a consistent "big 6" became apparent across the three time periods: justpaste.it; IS's own server; archive.org; sendvid.com; YouTube; and Google Drive. These six domains accounted for 83 percent, 70 percent, and 67 percent of the URLs in the February, March, and April sampling periods, respectively. However, there was a noticeable declining trend in the use of justpaste.it and IS's own servers. Between them, this accounted for 40 percent of URLs in February declining to only 18 percent by April. At around that time the Amaq News Agency website had come under repeated attack, which may have been responsible for its relative downgrading.[47] Use of sendvid.com and archive.org varied across the time periods, while Google Drive and YouTube were consistently heavily used. In fact, YouTube use showed an increasing trend (7 percent, 11 percent, and 12 percent, respectively). The remaining URLs (17 percent in February rising to 33 percent of URLs by April) were spread across a wide variety of mainly, although not exclusively, content upload sites (thirty-four in total).

The proportion of IS propaganda successfully taken down was also analyzed. The takedown rate (as of 12 April, 2017) was 72 percent, 66 percent, and 72 percent for the February, March, and April samples, respectively. Overall, 30 percent of links were still live on 12 April. This suggests that takedown activity was relatively rapid (occurring over a matter of days after propaganda was posted) and widespread (across a multiplicity of sites and platforms).

Conclusion

The costs for most pro-IS users of engaging on Twitter (in terms of deflated morale, diffused messages and persistent effort needed to maintain a public presence) now largely outweigh the benefits. This means that the IS Twitter community is now almost non-existent. In turn, this means that radicalization, recruitment, and attack planning opportunities on this platform have probably also decreased. However, a hard core of users remain persistent. In particula[...]nt in a daily cycle during o[...]within 24 hours, but not befo[...]

This arti[...]e not the only jihadists[...]wer levels of disru[...]al media platforms, conte[...]le it appears that official IS[...]termined.

The Tele[...]creating here in slightly [...]wer profile platform than Twi[...]e.g., provision of a

attributes from the perspective of cutting down on the numbers of users exposed to IS's online content and thereby in a position to be violently radicalized by it. On the negative side, this may mean that Telegram's pro-IS community is more committed than its Twitter variant. Also, while IS's reach via Telegram is less than it was via Twitter, the echo chamber effect may be greater as the "owners" of Telegram channels and groups have much greater control over who joins and contributes to these than on Twitter. Another aspect of Telegram that's doubtless also attractive to pro-IS users is its in-platform content upload and cloud storage function(s). While Telegram restricts users from uploading files larger than 1.5GB—roughly a two-hour movie—it provides seemingly unlimited amounts of storage.

In terms of proactive steps taken by Telegram with respect to IS and their supporters' use of their service, in December 2016, Telegram established a dedicated "ISIS Watch" channel, which provides a running tally of numbers of "ISIS bots and channels banned" by them. On 11 March, 2017 a message on the channel stated "Our abuse team actively bans ISIS content on Telegram. Following your reports, an average of 70 ISIS channels are terminated each day before they reach any traction." Between January and May 2018, the average number of terminations per days had jumped sixfold to 422. All told, Telegram claims to have banned 106,573 "ISIS bots and channels" in the period December 2016 to 31 May 2018, with May 2018 (9,810) having the highest number of bans yet recorded.[49] While it is clear therefore that Telegram routinely bans pro-IS users, channels, and bots, interpreting the numbers that Telegram has supplied is difficult absent knowing the overall numbers of users, channels, and bots actually active on the platform at any given time. Also worth pointing out is that in addition to exploiting the channels feature, IS began taking advantage of Telegram's groups function around summer 2017. So-called Supergroups allow for intra-group communication among up to 30,000 members[50] and like all other group chats on Telegram are private among participants; Telegram does not, in other words, process requests, including termination requests, related to them.[51]

Recommendations

The recommendations arising from this analysis are threefold. First, modern social media monitoring systems have the ability to dramatically increase the speed and effectiveness of data gathering, analysis, and (potentially) intervention. To work effectively, however, they must deploy a combination of suitable technology solutions, including analytical systems, with trained human analysts who are versed in the relevant domain(s) and preferably also the appropriate languages. This is particularly the case where an adversary is actively trying to evade tracking efforts. Technology such as Method52 assists by allowing the analyst to rapidly develop new analytical pipelines that take into account day-to-day changes in modes of operation. However, technology cannot detect such changes; these can generally only be spotted by a human well-versed in the particular domain of interest.

Second, some IS supporters remain active on Twitter. Content disseminators using throwaway accounts could probably be degraded further—although this may have both pros (e.g., detrimental impact on last remaining significant IS supporter Twitter activity) and cons (e.g., further degradation of Twitter as a source of data or open source intelligence on IS).

that a focus on IS should be dispensed with, but the significantly less-impeded online activity of HTS is surely an important asset for them and worth monitoring. Because data collection and analysis of other terrorist groups and their online platforms has been neglected, very few historical metrics are available for comparative analyses; this should be guarded against in future too.

Future research

Finally, some comments as regards future research. Our Other Jihadist category was a convenience sample of non-IS jihadist accounts. It is therefore proposed to replicate the present research, but with a larger and more equal sample of HTS, Ahrar al-Sham, and Taliban accounts. This would allow for a more systematic and comparative analysis of the disruption levels for a range of non-IS jihadists, including those with a significant international terrorism footprint (i.e., HTS), groups with a significant national and regional terrorism profile (i.e., Taliban), and a party to the Syria conflict (i.e., Ahrar al-Sham).[53] Such an analysis could help to ascertain the vibrancy of their contemporary Twitter communities and Twitter out-linking practices, and allow their preferred other online platforms to be identified.

Additional research is also clearly warranted into the wider violent jihadist online ecology. Wider and more in-depth research into the following is therefore recommended:

1. patterns of use, including community-building and influencing activity;

2. levels of disruption on other platforms besides Twitter, including other major platforms such as YouTube, but also other smaller or more obscure platforms, such as justpaste.it and others.

Analysis of pro-IS and other violent jihadist activity on Telegram and comparing this with our present findings is suggested too. It would also be worthwhile analyzing out-linking trends on Telegram to determine how the functionalities of different platforms have an impact on linking practices.

Acknowledgment

22 By early April 2017, the research had reached the stage where there was complete access to IS's main Twitter propaganda apparatus. This enabled the semi-automated system to determine what IS and supporter tweets would be linking to before those tweets were sent. It is thought that this occurred several hours before Twitter themselves become aware of these accounts and their tweets. Much of this may have been due to the research team being able to access data and intelligence across multiple sites, allowing early prediction of tweet material, where Twitter's disruption team were likely restricted to monitoring their own platform only. The system was thus able to immediately identify when an account disseminated one of these propaganda links on Twitter. It was then possible to capture the rate and speed of suspension.

23 It should be noted that this date was chosen at random. Propaganda represented in this graph had no relation to the chemical attack on the town of Khan Shaykhun, also on 4 April, as content was produced by IS on Monday 3 April 2017.
