Abstract

The payoff of many credit derivatives depends on the level of credit spreads. In particular, credit derivatives with a leverage component are subject to gap risk, a risk associated with the occurrence of jumps in the underlying credit default swap spreads. In the framework of first passage time models, we consider a model that addresses these issues. The principal idea is to model a credit quality process as an Itô integral with respect to a Brownian motion with a stochastic volatility. Using a representation of

Notes

¹Since 2009, following an initiative of the International Swaps and Derivatives Association to facilitate netting, credit default swaps are nowadays entered into with standardised premiums of 25, 100, 500 or 1000 basis points. As a consequence, entering into a CDS normally requires an upfront premium to be paid. In the analysis of our model, we neglect the changes in market quoting conventions, since the qualitative results on the spread dynamics are not affected.

²The term credit spread also refers to the yield spread, which is the yield difference of defaultable and default-free zero-coupon bonds of the same maturity. There are some subtle differences between yield spreads and CDS spreads, mainly due to factors such as liquidity of the underlying and restrictions regarding short-selling. However, we assume that stylised facts of the yield spread term structure that can be related to the credit risk component of the underlying entity apply to the CDS term structure as well.

³A credit-linked note (CLN) is a note or bond paying an enhanced coupon to an investor for bearing the credit risk of a reference entity; see Bielecki and Rutkowski (2002, section 1.3.3) for a general description.

⁴The requirement P -a.s. ensures that P -a.s., as will become clear later on.

⁵For notational simplicity we compute an matrix of default probabilities; other setups of time points and time-to-maturities are possible.

⁶Actually, \mathbb{P}^i is not a martingale measure, hence for efficiency

⁷If the interest rate moves, the volatility of the underlying asset moves, hence for efficiency
