## ABSTRACT

Identity theft—one of the fastest growing crimes—results in considerable financial losses as well as time spent to restore credit and prevent future attacks. While scholars have begun to devote more attention to identifying the factors that increase risk of identity theft, little is known about the aftermath for victims. Using data from the Identity Theft Supplement to the National Crime Victimization Survey, we address this gap in the literature. Results indicate that, in addition to financial losses and loss of time, victims also experience emotional (e.g., depression) and physical (e.g., poor health) symptoms. The implications of these findings for theory, research, and policy are discussed.

# Notes

1. We are aware that the sample used here is whittled down significantly from those originally included in the household-level NCVS. This raises possible concerns about bias in our estimates—namely, that respondents who completed the ITS are unique from those who completed other portions of the interview or who did not complete the study at all. These concerns are lessened by the knowledge that the original researchers found little or no bias stemming from nonresponse in the ITS estimates (Harrell & Langton, 2013).
2. The NCVS measures income as a categorical variable rather than a continuous variable.
3. Analyses run prior to imputation produced results identical to the analyses run following imputation; therefore, biased results as a product of imputation are unlikely.
