Abstract

This empirical note utilizes US annual data from 1949 to 2007 to examine the causal relationship between biomass energy consumption and real gross domestic product (GDP) within a multivariate framework. Toda-Yamamoto causality tests reveal unidirectional causality from biomass energy consumption to real GDP supportive of the growth hypothesis.

Keywords:

biomass energy consumption

Granger-causality

real GDP

Notes

¹Energy Information Administration, Monthly Energy Review, July 2008.

²National Renewable Energy Laboratory, www.nrel.gov. [Balat and Ayar \(2005\)](#) survey world trends toward biomass energy use while [Kaygusuz \(2009\)](#) provides a review of the production, consumption, and technologies for biofuels in developed and developing countries.

³The US Department of Energy (DOE) undertakes a number of programs to facilitate the development of biomass as an energy source: The DOE Biofuels Program develops new technologies to utilize low-cost cellulosic biomass into ethanol; the DOE Biopower Program addresses biomass-based electricity generation systems and the development of sustainable energy crops; and the DOE Regional Biomass Energy Program provides cost-sharing and other support to state and local governments in the production and use of biomass energy.

⁴Much of the discussion of the hypotheses and related literature is drawn from the survey article on the causal relationship between energy consumption and economic growth by [Payne \(2010\)](#).

⁵The following are the dates in which data is reported by the Energy Information Administration (www.eia.doe.gov) for the various subcategories of biomass energy consumption: wood (1949–2007), waste (1970–2007), and biofuels (1981–2007).

⁶The use of real gross fixed capital formation as a proxy for capital follows the work of Soytaş and Sari (2008) and citations therein.

⁷Test statistics for Granger-causality have the standard asymptotic distribution to draw valid inferences.
